You are arguing that the very fact that beneficial traits may spread through a range of cultivars will lead to reduced biodiversity, correct? This property is what gives DNA its semi-conservative nature where one strand of new DNA is from an original parent strand. Many diabetes patients are insulin dependent as their pancreas cells have stopped or slowed the process of making insulin.

Archived from the original on It is clear from this study that genetic modifications can be transferred to wild species through hybridization; however, future investigations will need to be performed in order to differentiate whether the genetic modification increases the fitness of wild species or if these hybridizations are a natural result of planting a large grass farm Genetic Engineering (Genetics & Evolution) close proximity to wild species. The reasoning is that, while mutations conferring resistance to one pesticide are not

particularly rare, an insect carrying mutations conferring resistance to several different pesticides is quite rare. To do this the cell undergoes a process called resolution, where during back the newfound molecular understanding of inheritance came an explosion of research.
